APPENDIX C - PHASE TWO SUMMARY SHEETS

APPENDIX D - PHASE TWO VOLTAGE SHEETS

Distribution List

I. PURPOSE

The purpose of this program is to determine the detailed requirements for programmed, automatic field maintenance testing of all types of Army electronic prime equipments and systems. From a study of these data, the feasibility of utilizing the building-block concept in implementing these test requirements will be determined.

II. ABSTRACT

This study is concerned with the review of Army technical manuals and related documents to determine the requirements for an integrated effort to automate Army electronic equipment in the field. The program has been divided into two phases. The first phase covers a comprehensive review and tabulation of Army prime electronic equipment test parameters, and of associated test equipment parameters, coordinated into an evaluation of the capability of building block modules in testing these parameters more efficiently than with present test equipment. The second phase covers a less comprehensive review and tabulation of additional Army equipment, performed under redirection of the program, as a data collection both to illustrate the usefulness of the EAM system in general and to demonstrate the potential of the building-block module concept.

III Publications, Lectures, Conferences and Reports (cont.)

C. CONFERENCES

On 6 September, 1962 a conference was held between Mr. Thomas M. Childs of USASRDL, Ft. Monmouth, and Mr. Ralph Megerle of Aerojet-General Corp., Azusa. The purpose of the conference was to discuss and initiate changes in the technical scope of the Building Block Contract. The changes which resulted from that conference were drawn up and transmitted for formal approval by the U.S. Army Signal Research and Development Laboratories.

A conference was held on 9 February, 1962 at Aerojet-General Corp., Azusa, California for the purpose of reviewing the Aerojet facilities and the progress to date on the study program. The following conferees were in attendance:

From USASRDL,

Mr. Thomas Childs

Mr. Alex Rosenblum

From Aerojet,

Mr. Marvin Boatright

Mr. Harry Smith

Mr. Paul Burk

Mr. Bestwick Vinton

In view of the receipt of Proposal Request 62-FIG/D-9263, which is concerned with the continuation of the Building Block Study, plans for the continuation of the program were discussed. Specific charts and graphs, which indicated some of the study results, were presented to Mr. Childs and Mr. Rosenblum. These charts, and others, are reproduced in this final report.

Mr. Alex Rosenblum of USAELRDL visited Aerojet General Corp., Azusa the week of 4 February, 1963 to review the program and make recommendations for the remaining work to be done on the contract, especially for the final report.

A general conference was held 7 February between Mr. Rosenblum and the Aerojet Support Systems personnel. The following results were agreed upon:

1. Preparation of the final report would begin immediately.
2. All tabulation of Air Force equipment would be discontinued.

III Publications, Lectures, Conferences and Reports (cont.)

C. CONFERENCES

On 6 September, 1962 a conference was held between Mr. Thomas M. Childs of USASRDL, Ft. Monmouth, and Mr. Ralph Megerle of Aerojet-General Corp., Azusa. The changes which resulted from that conference were drawn up and transmitted for formal approval by the U.S. Army Signal Research and Development Laboratories.

A conference was held on 9 February, 1962 at Aerojet-General Corp., Azusa, California for the purpose of reviewing the Aerojet facilities and the progress to date on the study program. The following conferees were in attendance:

From USASRDL,

Mr. Thomas Child

Mr. Alex Rosenblum

From Aerojet,

Mr. Marvin Boatright

Mr. Harry Smith

Mr. Paul Burk

Mr. Bostwick Vinton

In view of the receipt of Proposal Request 62-EIG/D-9263, which is concerned with the continuation of the Building Block Study, plans for the continuation of the program were discussed. Specific charts and graphs, which indicated some of the study results, were presented to Mr. Childs and Mr. Rosenblum. These charts, and others, are reproduced in this final report.

Mr. Alex Rosenblum of USAELRDL visited Aerojet-General Corp., Azusa the week of 4 February, 1963 to review the program and make recommendations for the remaining work to be done on the contract, especially for the final report.

A general conference was held 7 February between Mr. Rosenblum and the Aerojet Support Systems personnel. The following results were agreed upon:

1. Preparation of the final report would begin immediately.
2. All tabulation of Air Force equipment would be discontinued.

Report No. 2535

III Publications, Lectures, Conferences and Reports, C (cont.)

3. In lieu of the Air Force equipment, Mr. Rosenblum would supply, prior to the second week in March, data on newer Army Prime Equipments such as:

|           |            |
|-----------|------------|
| AN/GRC-50 | AN/PRC-25  |
| AN/GRC-66 | AN/GRC-106 |
| AN/VRC-12 |            |

4. Contractually Aerojet was to deliver the following.

- a. Final Report
- b. EAM cards and print-out of all items tabulated.

5. Aerojet will send an engineer, if conditions permit, to USAELRDL to describe the tabulating system.

6. The following tentative time scale will follow.

- a. Conclusion of Engineering Services - 28 February 1963
- b. Additional study documents from USAELRDL - 7 March 1963
- c. Documentation system presentation - 23 April 1963
- d. Final Report, draft copies - 1 May 1963
- e. Approved Final Report - 10 June 1963.

D. REPORTS

In the performance of this contract, 22 monthly progress reports have been published, numbered L0447-01-1 through -22.

Also in the performance of the contract six quarterly reports have been published, numbered 0447-01-1 through -6.

IV. FACTUAL DATA

A. ORIGINAL PHASE

The building block study program was initially a test requirement survey of prime electronic equipment and test equipment used by the Army, and use of the data thus found in illustrating the adaptability of automatic and

IV Factual Data, A (cont.)

semi-automatic building-block test modules to field testing. Additionally, the feasibility was to be proven with breadboard tests, and then preliminary design criteria drawn up for actual system modules. The preparation of an integrated testing system to perform field testing of the Army electronic equipment was the design goal, using building block test modules in automatic operation. This system was to employ programmed test input measurement criteria, controlled by pre-punched tape or IBM cards, which would automatically select the specific test point for measurement. Then the system would complete the test cycle by recording the measurement results on punched tape or actual print-out, thus furnishing a permanent record.

The development of the above-described integrated building-block test measurement system must be based on a comprehensive review of the measurement data and associated considerations of actual usage of the prime electronic equipment and the test equipment used by the Army in the field.

1. Nature of the Data Desired

The feasibility evaluation of the building-block module testing system logically begins with the testing characteristics of the prime electronic equipment. This information is best supplied from the Army's technical manuals, which were the basic source indicated for use in the program. The data from the manuals requires tabulation (Aerojet Form B511:61-1133 was drawn up) as a method to extract the data swiftly and accurately for automatic testing purposes and also as an aid in evaluation studies. For this reason the recording of the data from the work sheets to IBM cards provides an ideal storage and recall medium for automatic reference. The test parameters were broken into four categories: power requirements, trouble shooting, alignment, and final test. Also the test equipment list specified for maintenance of each particular piece of prime equipment was included.

The actual extremes of values to be measured and the accuracies required were to be tabulated. These measurements are (1) power in some multiple or fraction of watts, (2) current in amperes or fractional amperes,

IV Factual Data, A (cont.)

(3) voltage in some multiple or fraction of volts, (4) frequency in cycles or some multiple, (5) pulse time or pulse width in some fraction of seconds, and, (6) resistance and impedance in ohms or some multiple of ohms. It is understood that these measurements are to be taken of test points, or input or output terminals, etc., of the equipment and not of dismantled sections or individual components. The building-block testing system is conceived for use in field maintenance testing and would obviously be applied to system or whole unit tests.

The data obtained will be the basis for designing the test modules, both as to range and as to function. Also the data is necessary to furnish information on the overlap in the test equipment presently in use, which is important for efficiency and cost studies. Other factors need to be known, such as the relative number of each type of equipment in use, or population factor, and the complication of the measurements, or complexity factor.

Discussion of Basic Building Block Modules

The concept of building blocks as components of field test equipment, especially in the third and fourth echelons, is a sound one. The fabrication of basic modular oscillator, amplifiers, and voltage conditioners, plus suitable packaging them, will result in a reduction of field test equipment items and also permit a modernization of such equipment. The minimizing of redundancy or overlap will result in a reduction on the total items of test equipment.

The establishment of firm criteria in the design of the modules provides a solution to the problem of redundancy in types of equipment.

In usage, the building blocks will feature maintenance based on unit independence. The failure of one building block will not effect the others in the integrated test setup. Interchangeability and replacement of faulty modules will be a simple plug-in operation. Also, the modules will feature high reliability through extensive use of solid-state circuitry, which will insure a minimum of module failures.

IV Factual Data, A (cont.)

The building-block systems are planned to be integrated assemblies of detachable test modules, designed to test some certain prime equipment types. The exact division of specific equipment to a certain building-block system or setup, and the division of measurement functions, would be dependent upon at least a completion of the preliminary design, which is beyond the scope of this program.

The automatic and semi-automatic features planned for the building-block system give the dual advantage of nearly foolproof testing and of furnishing a permanent test record. The automation is to be accomplished through the use of (1) programmed inputs by means of a pre-punched Mylar tape or equivalent tape-block reader (2) interface adapters to reconcile the test points with the test modules, and (3) digital print-out of the output and test point readings.

Figure 1 illustrates the block diagram of the modular concept in the automated test setup, drawn up in general form. Numerous modifications could be made to accommodate many test configurations. The necessary test setup and operating procedure for any maintenance test must be outlined in a revision to the appropriate technical manual.

In actual use the correct building blocks will be selected for stimuli generation and response measurement, and then contact closures initiated by block readers would apply the test stimuli to the equipment. The resulting response would then be conditioned first to an analog voltage and then digitalized and entered into a comparator. The test limits in the comparator will have previously been set by the block reader information. The test results of the comparison will then be indicated and printed.

The programming indicated in the block diagram of Figure 1 may be either internal or external. Any automatic test configuration should have the ability to make use of the portable automatic data-processing developed for the Field Army. The FIELDATA Equipment Program has produced mobile, general-purpose digital computers such as the MOBIDIC, the BASICPAC, and the COMPAC.

IV Factual Data, A (cont.)

A self-contained, highly portable programming unit would perform the essential functions of test procedure operation and some limited trouble shooting. A larger external unit, however, would afford additional memory capability, and a greater potential for investigation of specific failures or additions to the testing program.

Application of the FIELDATA Equipment computer to the building block system would yield a design utilizing the 1-megacycle clock rate of the computer, and the 38-bit word length.

a. Modular Design Features

Basic criteria for the preliminary design of the building block system developed from the survey of 60 representative pieces of tactical electronic equipment. The derived data provided significant information concerning the types of modules and their indicated parameters.

The modular concept will incorporate standard types of equipment in the simplest form possible, as shown in the list of circuits below:

- (1) Single-stage voltage amplifiers
- (2) Oscillators
- (3) Rectifiers
- (4) Filters
- (5) Mixers
- (6) Modulators and demodulators
- (7) Pulse formers

With these basic circuits, plus essential special circuits, a test setup will be created. The various building blocks would be solid-state circuitry encapsulated for protection. The blocks might range in size from fractions of a cubic inch to several cubic inches, depending upon the function. The blocks could be combined into a specific test function by plugging into a function "drawer". This function drawer may be considered

IV Factual Data, A (cont.)

a prime module, and the plugged-in blocks as submodules. An illustration of a submodule application would be an oscillator for audio-frequency tests. The prime audio-oscillator module could accommodate a discrete number of frequency submodules, depending upon the test requirements. In this case, the prime module simply acts as a package to transfer power to the blocks and as an interface to carry signals to and from the various blocks as required.

Similarly, the voltage measurement module would accept a discrete number of voltage amplifiers. Factors such as the range and accuracy of the voltages to be measured, will determine the number of submodules required.

The complete battery of test requirements would be accommodated by the building block module system. The number and sizes of the modules would have to be established. Test procedures will undergo revision to match the new testing methods. For example, third- and fourth-echelon testing will, in many cases, no longer be concerned with wave shapes. Peak and half-power points, or other points of slope change, will be sampled and measured as voltages. Reasonable assurance that the wave shape is correct would be obtained through agreement of the sampled voltages with established limits. In the examination of an intermediate frequency amplifier bandwidth, for example, it is not necessary to examine the entire wave shape. The probability is that the frequency bandwidth between the half-power points and the voltage measurement at the peak will establish the operating characteristics of the amplifier.

Miniaturization techniques have been advancing rapidly. These new techniques will permit modules to be made smaller, thus approaching microminiaturization. It may be planned to adapt the smaller modules or submodules into the system in a manner to minimize obsolescence.

Certain pieces of test equipment are basic. Any plan to design test equipment into modules and effectively replace a variety of similar voltmeters, for example with a new standard design, should be well based on present intended usage and future projections, to warrant the redesign. The survey of test equipment in general Army use shows considerable overlapping

IV Factual Data, A (cont.)

of measurement functions. This redundancy can be largely eliminated in the design of the modules.

b. Modular Design Preparation for the RT-66/GRC

The designing of a building-block testing system requires an organized effort applied to a logical program. In this study the following six steps were developed for the preparation of the building block system:

(1) Project Planning

Preparation of detailed plans for the study effort and schedules for the task groups.

(2) Survey of subsystem requirements, where these are the areas or subsystems for survey.

- (a) Army Organization and Logistics
- (b) Programming and Automatic Controls
- (c) Test Instrumentation
- (d) Human Factors

(3) Subsystem Feasibility Investigations, according to the following:

(a) Detailed investigation of the feasibility of the concepts developed during the Survey of Subsystem Requirements in Step (2) above.

(b) Breadboard circuitry designed and tested for concept evaluation.

(4) Preliminary System Integration

(a) The tentative requirements generated in the Survey of Subsystem Requirements in Step (2) above, developed into a preliminary system concept.

IV Factual Data, A (cont.)

(b) Results of the breadboard circuitry tests in Step (3)b, above.

(5) System Application Exercise

(a) Feasibility evaluation of system concepts through theoretical analysis.

(b) Feasibility evaluation of system concepts through practical experiments with actual Signal Corps equipment. (The RT-66/GRC Receiver/Transmitter and its associated test equipment, per TM11-289 was the first item of equipment chosen for this purpose).

(6) Summary of Final Requirements

(a) Evaluation of the preliminary work

(b) Statement of requirements for the automatic test system.

c. Technical Considerations in the Modular Design for RT-66/GRC Test Equipment

The analysis performed in the preparation of preliminary design criteria illustrated the technical considerations necessary in developing a building-block subsystem. The following two sub-sections, dealing with the test instrumentation subsystem firstly, and circuit design problems secondly, will clarify many of the considerations.

(1) Test-Instrumentation Subsystem Analysis

The "Test-Instrumentation Subsystem Study" covers advanced techniques for test instrumentation, and will determine the manner and agree to which the original requirements for test instrumentation are affected by these techniques. This report establishes many of the basic parameters for stimuli generation and response monitoring. This task has been divided into the following subtasks for circuit investigation:

Voltage conditioning

Dynamic Frequency Deviation

IV Factual Data, A (cont.)

Variable Reactance Oscillators  
Radio-Frequency Power Measurements  
Frequency Measurements  
Distortion Measurements  
Methods of Signal Switching

During the project planning phase, four areas of system investigation were defined as follows:

Interface with the Army FIELDATA System  
Verification of the RT-66/GRC Final Test Procedures  
Revised Test Procedure Verification  
Final System Integration

(2) Circuit Design and Subtasks

The first step in determining the input-output goals for the test modules (as given in the subtasks for circuit investigation) is the detailed study of the methods now used for final testing of the RT-66/GRC. In general, the automatic testing will follow the basic procedures of the manual testing. Deviations are allowed in two cases. First, if it is unreasonably difficult, by automatic testing techniques, to perform a given measurement in the same manner as manual testing, different procedures should be investigated. Secondly, in those areas where the automatic equipment can perform desirable tests that are impossible with manual equipment, these tests should be added.

A list of tests has been prepared from the final test as given in TM11-289 (RT-66/GRC)

Physical Tests and Inspection  
Sensitivity  
Overall Selectivity  
Limiting Action  
Squelch Sensitivity  
Regeneration and Audio Output

R-F Power Output  
Modulation  
Frequency Comparison  
Signaling Oscillator Frequency  
Operational.

The key to the success or failure of the building-block concept for testing F-M communications equipment lies in the modular, programmable F-M signal generator. This is true for two reasons. First, it is evident that the advantages of using automatic testing are much greater in the testing of the receiver portion of the equipment than in the transmitter testing. The receiver testing can be made virtually fully automatic after a few simple preliminary adjustments are made. The transmitter, by its nature, will probably always require a certain amount of operator control. Secondly, the modular F-M signal generator replaces the AN/URM-48 which is the largest and most complicated single piece of test equipment used in the manual testing of the RT-66/GRC. For these reasons, the F-M signal generator was the first module investigated in this study program.

The requirements for the F-M signal generator can be stated quite simply as follows. The instrument must be capable of generating a 1 or 2  $\mu$ v of signal, modulated or unmodulated, at frequencies of 20.5, 23.5, 25.5, 27.5, 33.5, 36.5, 38.5, 46.5, and 52.5 mc. These frequencies will meet the requirements of RT-66/GRC, RT-67/GRC, and RT-68/GRC. The basic design must be capable of operating at all frequencies required by any F-M equipment of interest. The modulation is at 1000 cps with a deviation of 15 kc.

The design of any F-M signal generator is complicated by two conflicting requirements. First, the carrier frequency must be held to very small tolerances. Secondly, the frequency must be varied in accordance with the amplitude of the modulating frequency. A highly stable, crystal-controlled oscillator will satisfy the first requirement. It is, however, not possible to directly frequency-modulate a stable, crystal-controlled oscillator.

IV Factual Data, A (cont.)

Two basic schemes are used to generate F-M signals with high carrier frequency stability. The first of these uses phase modulation and the second uses direct frequency modulation. There is no difference between the signals generated by these two methods if the modulation is accomplished properly.

Phase modulation is the classical method for generating FM (this was the system used by Armstrong in the 1930's). There are two basic problems which generally complicate the design of a phase modulator. The first of these problems is caused by the fact that the output frequency of a phase modulation is affected by the modulating frequency as well as its amplitude. For this reason a corrective network is normally used. Since only one modulating frequency is used in the modular F-M signal generator, no corrective network is required. The second problem is caused by the relationship between linearity and modulation index in phase modulation. The maximum allowable modulation index with good linearity is 0.5. Modulation index is the ratio between the maximum frequency deviation and the minimum modulating frequency. For good linearity, therefore, the frequency deviation at the point of modulation must be less than half as great as the lowest modulating frequency. In a commercial transmitter, the lowest modulating frequency may be as low as 100 cps. The maximum frequency deviation may, therefore, be only 50 cps. Since the output frequency deviation must be 75 dc, the modulation must occur at a frequency 1500 times below the transmitter frequency. A great many frequency multipliers must therefore be employed. The requirements for the modular F-M signal generator are much less stringent on this point. The lowest, and only, modulating frequency is 1000 cps. This allows a frequency deviation of 500 cps. Since the output deviation is 15 kc, a factor of only 30 is required between the modulator and the output.

Direct frequency modulation is obtained by varying the frequency of an oscillator which is not crystal-controlled. In order to keep the carrier frequency within tolerance, the average output frequency is

IV Factual Data, A (cont.)

compared to that of a reference crystal-controlled oscillator. If the frequencies are not identical, a correcting voltage is fed back to the uncontrolled oscillator. There are two commonly used methods for obtaining frequency stability in direct frequency modulation. One of these is the Crosby, or discriminator, method; the other is the phase detector method.

The phase modulation system is preferable to direct frequency modulation in the modular F-M signal generator for two reasons. First, phase modulation is simpler and will require fewer components. This is particularly true because of the simple requirements of the modular F-M signal generator. Secondly, the linearity in the phase-modulation system is not dependent on any components. The linearity of the direct frequency-modulated system is dependent on the characteristics of the device which is used to vary the frequency as a function of voltage.

The tentative block diagram for the modular F-M signal generator is shown in Figure 2. Basically, the signal generator consists of two modules. One of these is common to all of the generators, no matter what the final carrier frequency might be. This module generates a 3.2-mc signal with a deviation of 15 kc at a modulation frequency of 1000 cycles. The other module is selected according to the test frequency required. Its output will also have a deviation of 15 kc at 1000 cycles.

An area of investigation recently initiated, apart from the RT-66/GRC, encompasses the use of diodes for signal switching. An example of a circuit to be breadboarded for a feasibility test is given in Figure 3. Any further work in this investigation should determine such parameters as:

Maximum Signal Frequency  
Ideal Signal Termination  
Switching Speed  
Crosstalk  
Miniaturization

IV Factual Data, A (cont.)

The circuit illustrated (Figure 3) consists of two switching diodes back-to-back, CR-1 and CR-2. During the "OFF" condition the junction of the two diodes must be positive. A positive voltage is applied through a resistance to provide a low impedance path between the junction of the two diodes, and ground through diode CR-3. CR-3 is conducting and grounds any signal. The positive voltage also ensures that CR-1 and CR-2 are cut-off.

In the "ON" condition, a negative voltage is applied at the control point which is sufficient, to override the positive voltage and cause CR-1 and CR-2 to conduct and cut-off CR-3. The control voltage may come from a flip-flop or the contacts on a tape reader. By application of the proper control voltage, either input will appear at either output. The amplifiers indicated restore signal level, isolate, or provide impedance match.

d. Basic Test Equipment

The test equipment called out in the technical manuals for use in testing the 60 pieces of prime electronic equipment surveyed is graphed for frequency of usage in Figure 4. The data, reduced from the IBM cards, serves to aid in the basic test equipment requirements. The number of modules required to perform the high-occurrence measurements, for example, may be estimated from the bar graphs in Figure 4. Figure 5 gives the separate number of times the equipment was specified for troubleshooting, alignment, and final test.

The equipment which is fundamental to the maintenance of Army electronic equipment, consists basically of the 14 items listed below.

- (1) Vacuum tube voltmeter
- (2) Radio-frequency signal generator
- (3) Frequency meter
- (4) Vacuum tube, transistor, and diode tester

IV Factual Data, A (cont.)

- (5) Audio-frequency signal generator
- (6) Oscilloscope
- (7) Output meter (DBM)
- (8) Radio-frequency wattmeter
- (9) Panoramic indicator
- (10) Spectrum analyzer
- (11) Pulse generator
- (12) Noise and distortion meter
- (13) Sweep generator
- (14) Pulse counter.

The 14 items above would not each become a building block module. Automatic testing represents an advanced concept. Digital test techniques have to be employed, replacing or supplementing analog test devices, and the test modules will vary significantly, for this reason alone, from the conventional test equipment.

- (1) High-Input-Impedance Voltmeters, or Electronic Multimeter

These devices measure alternating and direct-current voltages and d-c resistances. The ranges required may be summarized as follows:

|               |   |
|---------------|---|
| A-C Voltages: | 0.05 to 1000 volts, frequencies<br>of 30 cycles to 5 megacycles |
| D-C Voltages: | 0.05 to 2500 volts  |
| Resistances:  | 1 ohm to 50 megohms   |

These ranges were based on the tabulated data of the equipment under study. Accuracy for the measurements is nominally plus or minus 10%. Therefore, a system accuracy of plus or minus 3% will suffice. The input impedance should be as high as practical over all ranges.

Analysis of electronic circuitry reveals that the measurement of d-c voltages is accomplished by d-c amplifiers, with precision

IV Factual Data, A (cont.)

attenuated input at a high impedance, and low-impedance outputs driving a meter movement (0 to 1 milliamp). Since the modular conception of test equipment design visualizes the information being converted to a digital or binary-coded decimal for inline readout and printout, meters of the D'Arsonval type requiring a low-impedance source are not used.

The electronic multimeter, under these conditions, is reduced to a linear voltage amplifier, the output of which is an analog voltage, digitized for comparison and readout. In its simplest sense, such an amplifier is only a signal conditioner and the range of voltages it may condition is limited only by the accuracy requirements and the linear range of the amplifier module. This module becomes a compact package constructed entirely of solid-state devices.

(2) R-F Signal Generation

The Building Block Study, after the data on the various frequencies used in testing were reduced, revealed certain discrete frequencies most often used. Figures 6 and 7 list these frequencies. The modular concept, as applied in this instance, defines a signal generator which is a set of solid-state oscillators, crystal-controlled where required. Each oscillator building block will cover a practical group of frequencies. The output of these modules is programmable, and is flexible enough to meet all equipment requirements. Specific intermediate frequencies would be simple crystal-controlled oscillators such as 455 kc and 4.3 mc. Mid-band test frequencies would be selected to cover as many pieces of equipment as possible.

The output of these oscillators could be applied with variable attenuation, either to the antenna of a specific receiver (or some other test point within the receiver), or mixed with the attenuated output of a transmitter.

The frequency to be measured should be mixed with a known frequency, and the difference frequency processed through a counter.

IV Factual Data, A (cont.)

The digital comparator will take this information and compare it with the information from the programer. The results are then processes to the visual readout and printer, and the "go/no-go" circuit. For the lower frequencies there is no mixing, thus information can be applied directly to the counter.

To measure VHF, the incoming test frequency can be mixed with a beat frequency oscillator (bfo), which has a difference frequency of 10 kc. To maintain an accuracy of measurement within specifications (0.005-1%), the bfo can be a crystal- or tuning-fork-controlled oscillator, the tolerance of which can be maintained at 0.002%. The difference frequency (10 kc) can then be measured by a pulse counter, the 3-decade output of which will have a minimum accuracy of 1%. Since 1% of 10 kc is 100 cycles, and this error reflected back to carrier frequency would be 0.00005% at 200 mc, at 10 kc the error reflected back would be 1%. The stated error would then be the 0.002% error of the oscillator, plus the reflected error of 1%, or a total of 1.002%. Below this frequency, direct-frequency measurement can be made with a minimum readout accuracy of direct-frequency measurement can be made with a minimum readout accuracy of 0.1% and a maximum error of 1%.

(3) Audio-Frequency Signal Generator

Certain discrete audio frequencies are needed for audio response tests, modulation-percentage tests, and frequency-deviation tests. An audio oscillator continuously covering the entire range from 20 to 20,000 cycles is not required for field testing. Spot audio frequencies may be chosen which will perform the required checks. Following are the suggested frequencies, in cycles, based upon those required under this study contract: 250, 500, 1000, 2500, 5000, and 15,000.

One audio-frequency oscillator module, constructed of stable solid-state oscillators, may be packaged in a small convenient size. The various frequencies can be programmable, as well as the required voltages. This oscillator will supply signals directly to the equipment under test, or will modulate the R-F signal generator.

IV Factual Data, A (cont.)

A survey has been made of commercially-available, unit-packaged circuits which can be applied to each major plug-in building block. For example, some typical units are listed below:

- (a) Transistorized crystal oscillator       $1 \times 1 \times 1\text{-}1/8$  in.
- (b) Power supply unit  
(one per five oscillations)       $2 \times 2 \times 3$  in.
- (c) Tuning fork oscillator       $1\text{-}1/2 \times 1/2 \times 3$  in.
- (d) Crystal discriminator       $15/16 \times 3/4 \times 1$  in.

(4) Oscilloscope

Analog methods of display are not required for automatic or semi-automatic testing, because of the digital print-out or similar voltage recording. The automatic testing will require a lower operator skill level, in general, than would be required in the use of an oscilloscope. Modular-designed oscilloscopes present no design problems; the basic principles are well established.

(5) Output Meter

This is a low-power measurement device at audio frequencies. It is designed to rectify, at audio frequencies, and condition the receiver output signal to a voltage which is a linear representation of the input decibels referred to a standard power level. The design will closely follow the same lines as the voltage measurement modules. The input to the amplifier should take a dynamic range of from -60 to +40 dbm.

(6) Radio-Frequency Wattmeter

Radio-frequency power measurements from milliwatts to kilowatts may be measured with suitable attenuators. Calorimetric power meters adapted to a modular design contain a self-balancing bridge. The unbalance signal is amplified and applied to a comparison load resistor. The power supplied to the comparison load to rebalance the bridge is conditioned to an analog voltage which may be digitalized and compared to the limits.

IV Factual Data, A (cont.)

An additional method worth investigation, because of simplicity and reliability, is to couple the R-F power output of the unit under test to a lamp. The illumination of the lamp will be detected by a photodiode and amplified. The d-c output of the amplifier will indicate the amount of power. This information will be digitized as required.

(7) Panoramic Indicator

Panoramic indicators are widely used in the testing of frequency-modulated transmitters. An important part of the test procedure is the measurement of frequency deviation as a function of the modulation. The use of an oscilloscope in field testing, as a method of deviation measurement, would be discontinued with the use of building block test modules.

Panoramic indicators use automatic scanning and super-heterodyne-type circuits for the simultaneous visual analysis of both the frequency and amplitude of R-F signals. Such test instruments must use a calibrated external oscillator.

In the modular form, frequency-deviation measurements would never be displayed on an oscilloscope. If it is desired to measure the frequency deviation of some F-M transmitter, the transmitter antenna, through suitable attenuation, is mixed with the output of a R-F oscillator module of the correct frequency to produce a difference deviation frequency, assuming modulation has been applied. The IF thus generated is then fed to a crystal discriminator; next, the maximum output is measured by the analog to digital (A-D) converter. The output of the A-D converter is then presented to the comparator for limit checking, as well as to the readout circuitry.

(8) Distortion Measurement

At audio frequencies the percentage of distortion may be measured in a variety of ways. One method is suitable for automatic testing. The test frequency is applied to the equipment, and the output is phase inverted. The original test frequency and the inverted output are mixed. The resultant voltage contains only the harmonic elements.

IV Factual Data, A (cont.)

The resulting harmonic frequencies will be processed through a true rms meter circuit which will produce a d-c output that is dependent on the rms of the input voltage. This information will be converted to digital form and compared with the limits from the programer for the "go/no-go" circuit. The ability to measure distortion amounts of 5 and 10% is required.

(9) Spectrum Analyzers

Radio-frequency spectrum analyzers required in microwave applications in the kilomegacycle ranges are used chiefly to examine power in pulsed or continuous-wave radar and beacon signals. Such analyzers are designed for specific frequency bands. As an example, the AN/UPM-58 has the following characteristics.

|                                   |                             |
|-----------------------------------|-----------------------------|
| Frequency coverage                | 16,000 <u>+200</u> mc       |
| Measurable input pulse modulation | 0.2 to 2 microseconds       |
| Measurable repetition rate        | 100 to 10,000 pulses/second |

Although the design of such a specialized piece of test equipment would be possible in modular form, it is felt that the complexity of such a module, as well as its relative lack of use, would offset any advantages gained.

(10) Pulse Generators and Pulse Counters

Pulse generators as input stimuli equipment may be readily constructed of solid-state devices and packaged in building block form. Discrete pulse frequencies and pulse widths may be assigned and programmed as required for specialized test procedures.

Pulse counters can be designed from standard solid-state counter circuitry, and the information in digital form may be displayed or compared. The transfer of pulse heights into digital form may be accomplished by a gate which will pass pulse trains representative of the pulse height.

IV Factual Data, A (cont.)

(11) Sweep Generators

Sweep generators will be substituted in an automatic checkout system by sampling circuits which will measure waveforms at critical points. The waveforms as analog voltages may be handled in the same manner as other a-c voltages.

(12) Logistics and Support

The establishment of design standards and specifications for sizes will assure minimum-cost production and ease of replacement of individual modules and building blocks; standardization is the important aspect. The ultimate goal is to replace several hundred pieces of test equipment with a few dozen building blocks. Simplicity of the individual units will eventually bring the cost sufficiently low that it may become practical for the field army to discard, rather than attempt to repair, individual modules. However, reliability of individual blocks will be enhanced by careful design, simplicity, and encapsulation.

Self-checking will be an integral part of the test equipment. Every effort should be made to create a high degree of operator confidence. Additional considerations relating to automatic testing will be discussed in the appropriate sections.

3. Semiautomatic and Automatic Testing

a. Advantages of Automated Testing

There are many benefits to be gained in adopting automated test methods. The following five reasons illustrate some of the advantages.

(1) Lower skill level or less training will be required for operating personnel.

(2) Test results are more accurate.

(3) The testing time will be reduced.

IV Factual Data, A (cont.)

(4) Logistic advantages will be realized, due to the handling ease of the more compact test equipment and the reduced testing time.

(5) Repeatability of test results will be greater.

Concerning Item (5) above, many groups of tests must be performed in the same manner every time. Automatic testing will eliminate operator deviations, since procedures have often varied from operator to operator. A test might be skipped, should one operator question its necessity or validity.

Additional advantages of automatic testing are apparent; for example, a printout of the test becomes a permanent record of the results.

In analyzing the need for automatic testing, consideration must be given to the complexity of the equipment to be tested, as well as to how many pieces of equipment may be expected to require test and repair. It is axiomatic that the automatic test equipment must require less upkeep and repair than the equipment to be tested. Complexity of the tactical electronic equipment will directly affect the size and complexity of any automatic testing equipment.

Further consideration must be given to the availability of test points in current Army electronic equipment. Future design of electronic equipment should reflect the trend toward automatic testing by the inclusion of sufficient test sockets.

b. Rating

Any analysis concerned with the practicality and feasibility of semiautomatic or automatic testing must be concerned with the number of pieces of equipment to be tested and the complexity of these pieces of equipment. For this reason, considerable time was spent in setting up a "yardstick" in an effort to evaluate the two above factors and assign a priority to any considerations of automatic testing. Any such set of rules will have exceptions, and such exceptions will be noted as they appear.

IV Factual Data, A (cont.)

The Divisional Table of Operations and Equipment (TOE) was the source for the divisional number of pieces of equipment of each type. The pieces of equipment most numerous in one of the three divisional types was the number selected to be the population factor (P.F.). In other words, the totals in the Infantry, Airborne, and Armored Divisions were all checked. The highest authorized total appearing in any one of the three was the selected population factor number. This number was then divided by 1000.

The Aerojet study and tabulation of alignment and final testing was the source for the complexity factor (C.F.). The complexity factor was the tabulated sum of alignment and final tests. This whole number was then divided by 100 to arrive at a decimal quantity. Since the P.F. number was divided by 1000 and the C.F. number was divided by 100, this then gave relative weights to the two fractions.

Table 1 presents the results of subjecting 35 varied pieces of tactical electronic equipment to the rating system. Such a study indicates that, of the 35 pieces, the TA-312/PT telephone set is best suited for semiautomatic testing from the viewpoint of quantity within the division. However, from a complexity viewpoint, the electronic circuitry is quite simple. Adjustments of the TA-312/PT will tend to be more of a mechanical nature, requiring the replacement of such items as handset cords, batteries, or transmitter elements. Most of the testing, therefore, does not lend itself to automation.

The second and third items of Table 1, the AN/PRC-10 and the RT-196/PRC-6 (AN/PRC-6), are ideal, both from a quantity and a complexity factor. Of these, the RT-196/PRC-6 was selected for a rigorous examination.

Radio Set AN/PRC-6 (RT-196/PRC-6) is a miniature, low-power, battery-operated radio receiver and transmitter used for voice communication over short distances. It is intended for use when a compact, easily operated radio set is required. The technical characteristics are as follows:

|                    |               |
|--------------------|---------------|
| Frequency range    | 47 to 55.4 mc |
| Number of channels | 43            |

IV Factual Data, A (cont.)

|                          |                          |
|--------------------------|--------------------------|
| Channel width            | 100 kc                   |
| Channel separation       | 200 kc                   |
| Tuning method            | Preset to single channel |
| Type of modulation       | FM                       |
| Distance range (approx.) | 1 mile                   |
| Power output             | 0.25 watt                |
| Number of tubes          | 13                       |
| Intermediate Frequency   | 4.3 mc                   |

c. System Concepts

Figure 1 is the generalized block diagram of an automatic or semiautomatic test configuration constructed of building blocks.

(1) Building Block Categories

These modular building blocks fall into three distinct categories.

- (a) The interface (with electronic equipment), power and control group
- (b) The programer, comparator, and printer group
- (c) The stimuli generator and response measurement group.

Interface is interpreted to mean the adaptive circuitry and connections necessary for the transmittal of required stimuli and the reception of required response from the selected electronic equipment.

(2) Interface Category

The following items are in this category:

- (a) Necessary test probes
- (b) Required test socket connectors
- (c) Special components for signal matching and attenuation
- (d) Provision for the interconnection of the above items with one another and with the test instrumentation.

IV Factual Data, A (cont.)

The amount of interface adaptation required, and the complexity of such adaptation, is inversely proportional to the corresponding amount of test circuitry engineered into the design of the communication equipment. If all required test voltages are brought out to accessible test receptacles, interface problems with automatic test equipment are kept to a minimum.

Current types of tactical electronic equipment vary widely in the location and number of test points. Future standardization in this area should be one design goal. Many maintenance checks on field equipment require elaborate and time-consuming test-equipment setups, with the test itself requiring very little time.

The interface adaptor should be a separate interchangeable module in the building block program.

Methods of control fall within this same category, since some way of switching test signals to and from the communication equipment must be provided. This control equipment will be energized by a programer, and will be either mechanical or electrical switching (e.g., relays, diodes, or transistors).

Some method of programming the test sequence must be incorporated. Of the many methods available, such as Core, Tape, or Punch Cards, the most compact and trouble-free from a field-maintenance standpoint is the punched-tape block reader with Mylar tape. Such a tape reader may use tape containing many groups of tests. The tape may be updated, revised, and corrected rapidly by the substitution of new tapes made up in depot areas, or by splicing in the field area. Block readers are compact in design, may be made virtually foolproof, and lend themselves to modular construction. Such readers, once the test sequence is established, will advance automatically from test to test unless there are indications of trouble.

(3) Tape Programer Functions

The tape programer will perform these functions in an automatic test sequence:

IV Factual Data, A (cont.)

- (a) Apply necessary stimuli to the equipment under test
- (b) Connect necessary response conditioning equipment to the equipment under test
- (c) Supply the "go/no-go" comparator with the test limits
- (d) Define the sequence of the tests
- (e) Identify the test setup.

The first block in a test sequence may be designed to check the modules in both type and position as required for the sequence.

The programer, comparator, and printer group may be self-contained or, as had been mentioned earlier, may be taken over by the FIELDATA Equipment. Further study in this area is needed in order to define the conversion requirements.

Visual display and printout of test results are required. The operator requires visual display as a means of immediate performance evaluation, but printout of results is necessary as a form of permanent record. This permanent record could accompany each piece of equipment passed for return to service.

The use of a data printer in portable equipment is completely feasible because at least one subminiaturized data printer is available which is capable of printing 12 columns of parallel-entry data at a rate of two rows (two tests) per second. This particular unit measures 6-1/4 x 4-1/4 in. and requires an installation depth of 6-1/2 in.

d. Control

All modules should be programmed either internally or by a combination of internal and external control and switching.

Specific switching functions are performed by the control switching building blocks. Each building block consists of a differentiator circuit, a flip/flop circuit, and a solid-state switch. The switch closes upon

**IV Factual Data, A (cont.)**

receipt of a control-line level change, and opens upon receipt of a reset-line level change. The activation of the control and reset lines are dependent upon the program commands received from the programer/comparator/decoder unit.

Solid-state or diode switching should be utilized whenever possible. Certain cases of very low frequencies or ultra-high frequencies will certainly require mechanical relays. However, even mechanical relays have been miniaturized to permit compact design.

**4. Application of Modules to Testing Specific Equipment**

**a. Test Diagrams**

Several months ago it became obvious that a method for diagraming the tests in a clear, simple manner was needed. Figure 8 illustrates the resultant form of the diagrams, which permit a display of separate tests. In this manner, the modules required can be critically evaluated as to the possibilities for automation.

The next step was to rewrite a technical manual to comply with automatic test procedures. Many equipments were diagramed, and several were selected for revision of the final testing procedures to reflect an automatic test sequence.

The AN/PRC-6 was selected for extensive examination, since it could illustrate the required tests without extreme complexity. Figure 9 is a block diagram of the test configuration for the AN/PRC-6. From the diagrams, an automatic final test procedure evolved requiring the elements shown in Figure 10. Chapter 6, "Final Testing," in TM 11-4069 (the maintenance for the AN/PRC-6) was rewritten. The original sections, immediately followed by suggested rewritten sections, for a technical manual prepared for automatic testing are shown below.

**b. Automatic Final Testing - AN/PRC-6**

Original:

62. Test Equipment

---

IV Factual Data, A (cont.)

- (1) Electronic multimeter TS-505/U
- (2) Signal generator AN/URM-25
- (3) Signal generator AN/URM-48
- (4) Audio oscillator TS-382A/U
- (5) Frequency meter TS-174B/U
- (6) Panoramic indicator IP-173/U
- (7) Electronic multimeter ME-6A/U
- (8) Battery BA-270/U
- (9) Resistor, 49 ohms, 1/2 watt (noninductive)
- (10) Resistor, 600 ohms, 1 watt
- (11) Battery, 9 volts
- (12) Potentiometer, 1000 ohms (carbon disk)
- (13) Resistor, 450 ohms, 1/4 watt
- (14) Resistor, 15 ohms, 1/4 watt.

Automatic:

Test Modules

- (1) Voltage conditioner (input 0 to 10 volts)
- (2) Radio frequency oscillators (51.0 and 4.3 mc)
- (3) Audio frequency oscillators (1000 cycles, 12 kc and 30 kc)
- (4) Mixer, filter.

Original:

63. Test Conditions

- (1) VOLUME control in maximum clockwise position
- (2) EXT-OFF-INT switch in EXT position
- (3) Resistor, 600-ohm, connected between Terminal 5 of E2 and ground
- (4) Electronic multimeter TS-505/U connected across the 600-ohm resistor

IV Actual Data, A (cont.)

- (5) Power supply  
Filament, +1.5 volts  
Bias, -4.5 volts  
Plate +45 and +90 volts.

Automatic:

Test Conditions

- (1) VOLUME control in maximum clockwise position (operator function)
- (2) EXT-OFF-INT switch in EXT position (operator function).
- (3) All special attenuation and matching will be a part of an interface adapter.
- (4) Power supply may be the self-contained batteries or may be supplied by the test set.

Original:

64. Receiver Sensitivity Test

- (1) Connect signal generator AN/URM-48 through a 49-ohm resistor to J3.
- (2) Adjust the signal generator output to 1 millivolt at the receiver frequency.
- (3) Modulate the carrier with a 1000-cycle signal at a deviation of 15 kc, and measure the audio voltage across the 600-ohm resistor.
- (4) Turn the modulation off and measure the noise voltage across the 600-ohm resistor.
- (5) The ratio of voltages should be not less than 3 to 1.

Automatic:

Receiver Sensitivity Test

- (1) After programer is advanced to first test position, initiate tests.

IV Factual Data, A (cont.)

- (2) Programed R-F oscillator module output is applied to J3 at correct level.
- (3) Programed A-F oscillator module output (1000 cycles and 15 kc) is switched to modulate the R-F oscillator.
- (4) Audio output of receiver is applied to voltage conditioner. This voltage is digitized and temporarily stored.
- (5) Modulation removed by programer. Noise voltage and stored voltage, in (4) above, compared. The minimal 3:1 ratio is automatically determined and a "go" or "no-go" condition is indicated.
- (6) Automatic advancement to next test.

Original:

65. Selectivity Test

- (1) Remove V2 and connect signal generator AN/URM-25 to Pin 1 of the socket through a 0.01- $\mu$ f capacitor.
- (2) Adjust the signal generator to operate at 4.3 mc, unmodulated. Adjust the output for a reading of -1-volt dc between Test Point 3 and ground.
- (3) Double the output of the signal generator, vary its frequency to the low side and then to the high side of 4.3 mc. Record the frequency reading at which the voltage at Test Point 3 is -1 volt. These two readings are called the "two times down readings."
- (4) Repeat Step (3) above with 1,000 times the original input signal. These two readings are called the "1,000 times down readings."
- (5) The bandwidth should be as follows:

| <u>Times down</u> | <u>Total bandwidth (kc)<br/>(difference in readings)</u> |
|-------------------|--|
| 2                 | 70 to 90   |
| 1                 | 750 maximum  |

IV Factual Data, A (cont.)

Automatic:

Selectivity Test

- (1) Previous operator function on initial test setup has been to make connections to the tube socket V2 by means of a plug-in adapter. This adapter and the 0.01- $\mu$ f capacitor are additional portions of the overall modular interface adapter.
- (2) Programed 43. mc, unmodulated, is applied to Pin 1. The 43.-mc center frequency is automatically varied a specified amount below and above, and the resultant voltages at Test Point 3 are compared to limits.
- (3) Step (2) above is repeated with the wider frequency variation.
- (4) Automatic advancement with "go" condition.

Original:

66. Discriminator Characteristics

- (1) With no signal applied and filament switch S1 open (pulled up), measure the voltage at Test Point 4. This reading is called the bias.
- (2) Remove V2 and connect signal generator AN/URM-25 through a 0.01- $\mu$ f capacitor to Pin 1 of the socket.
- (3) Set the signal generator to operate at 4.3 mc, unmodulated. Depress S1 and adjust the signal generator output for full limiting (-6 to -7 volts at Test Point 3).
- (4) The voltage reading at Test Point 4 should be the bias  $\pm 0.3$  volt.
- (5) Adjust the signal generator to 4.325 mc and then to 4.275 mc. Record the voltages at Test Point 4.
- (6) At 4.325 mc, the reading should be the bias plus 6 volts; at 4.275 mc, the reading should be the bias minus 6 volts, the difference between the values should be less than 1 volt.

IV Factual Data, A (cont.)

Automatic:

Discriminator Characteristics

- (1) Bias reading at Test Point 4 is applied to voltage conditioner.
- (2) Refer to step (1) above in Selectivity Test.
- (3) The 4.3-mc output is increased a specific amount.
- (4) Test Point 4 voltage reading is compared to limits.
- (5) The 4.3-mc oscillator is varied to 4.325 and 4.275 mc. The voltages are compared to limits.

Original:

67. Transmitter Power Output

- (1) Connect the dummy load, consisting of a 49-ohm noninductive resistor, between antenna connector J3 and ground. Make the dummy load leads as short as possible.
- (2) Connect the VTVM across the dummy load.
- (3) Set the EXT-OFF-INT, switch to the INT position and depress the push-to-talk microswitch.
- (4) Operate the transmitter at 47.0, 51.2 and 55.4 mc. Measure the R-F output voltage across the dummy load at each of these frequencies. The output should be not less than 3.5 volts ac.

Automatic:

Transmitter Power Output

- (1) The dummy load is part of the interface adapter.
- (2) The voltage conditioner is connected across the dummy load.

IV Factual Data, A (cont.)

- (3) EXT-OFF-INT, switch and PUSH-TO-TALK switch are operator functions.
- (4) R-F voltage is conditioned and compared to limits.
- (5) Advance to next test on "go" indication.

Original:

68. Transmitter Static Deviation Test

- (1) Disable the AFC circuit by removing limiter tube V7 and disconnecting the bias at Terminal 7 of El.
- (2) Connect the 1,000-ohm potentiometer across the 9-volt battery, with the center contact of the potentiometer connected to Pin 4 of Test Socket J2, and the positive terminal of the battery to ground.
- (3) Adjust the potentiometer for zero volts bias. Set the transmitter frequency to 51.0 mc. Press the PUSH-TO-TALK switch and check the transmitter frequency with frequency meter TS-174B/U.
- (4) Adjust the potentiometer so that -9.0 volts is applied to Pin 4 of the test socket.
- (5) The frequency meter should read 51.4 mc.

Automatic:

Transmitter Static-Deviation Test

- (1) These functions of V7 removal and disconnection at terminal 7 of El will be accomplished automatically by adapters.
- (2) All connections described in Step 2 of the original will be made in the interface adapter.
- (3) PUSH-TO-TALK switch operation is an operator function. Transmitter frequency will be compared to a standard crystal-controlled oscillator and the amount of deviation will be counted.

IV Factual Data, A (cont.)

- (4) Automatic voltage adjustment. The change in frequency will be measured and compared.
- (5) Automatic advancement to next test on "go" indication.

Original:

69. Transmitter Dynamic Frequency Deviation Test  
(Using Panoramic Indicator)

- (1) Make a voltage divider; use a 450-ohm and a 15-ohm resistor connected in series. Place the voltage divider across the output terminals of audio oscillator TS-382A/U. The 15-ohm resistor should be on the low side.
- (2) Connect the audio output from across the 15-ohm resistor to Terminals 1 and 6 of terminal strip E1 in the radio set.
- (3) Connect panoramic indicator IP-172/U to read the frequency deviation of the radio set.
- (4) Connect signal generator AN/URM-48 to the panoramic indicator so that it will provide the heterodyne signal.
- (5) Set the audio oscillator to provide an output of 1,000 cycles per second at 1 volt.
- (6) Turn the radio set on and press the PUSH-TO-TALK microswitch.
- (7) The deviation should be between 12 and 30 kc.

Automatic:

Transmitter Dynamic Frequency Deviation Test

- (1) The voltage divider, as described in Step (1) above of the original procedure, will be part of the interface adapter.

IV Factual Data, A (cont.)

- (2) Connection to Terminals 1 and 6 of terminal strip E1 will be made on the initial setup.
- (3) An internal (to the automatic tester) oscillator will beat with the transmitter frequency. The audio oscillator will be mixed with the R-F oscillator.
- (4) The press-to-talk switch will be an operator function.
- (5) The deviation will be measured by a crystal filter and a frequency-to-dc converter. The representative voltage limits of 12 and 30 kc will be compared.
- (6) Completion of test series.

5. Major Items in Printouts

There were 60 items of prime electronic equipment reviewed and tabulated in the comprehensive survey first summarized.

Each item was tabulated on a separate sheet, and the resulting IBM cards were indexed by the item number. The coding and the column entries were identified according to the following system.

Sections under which information is tabulated are:

Code 100-199 - Power Requirements

Primary external power required (voltages, currents). If external power supplies are used, list voltage outputs and types of voltages with current requirements.

Code 200-299 - Trouble Shooting

List test equipment and special accessories required. List maximum and minimum resistances and voltages, other than zero and infinity, as normally indicated on trouble-shooting charts. (Example: Tube Base Readings)

IV Factual Data, A (cont.)

Code 300-399 - Alignment

List test equipment and special accessories. List discrete values or limits of test equipment readings and/or levels of function generators, along with tolerances (percentage of) for each alignment or adjustment operation. Omit operations of a mechanical nature.

Code 400-499 - Final Test

List as in Code 300-399, above.

Column Headings and appropriate entries are as follows:

Item - An identity number is assigned each component and is entered under this column.

Sequence - A number must be assigned each line of data. This number is to be in sequence and in the category previously stated.

Test Equipment Nomenclature - The identity number of the test equipment as given in the manual is entered in this column; also, identity numbers of accessories when given.

Function Description - Enter in this column the particular function occurring at the time of the specific test.

Function Code - When this is required, use code as given in Table 2.

Primary Values - Low or discrete and high.

Value - Lowest value or only value to occur during that portion of the test.

Unit - Abbreviated unit of measurement.

High value and unit.

Tolerance, percentage of - where limits are given, enter the limit in form of equivalent percentage.

Secondary Values and Remarks - Enter any additional information necessary or useful to the operation.

---

IV Factual Data, A (cont.)

Various codes were utilized to assist in condensing the information for collation. Tables 2 and 3 show the codes as explained in the above procedures. A function code of "213" would indicate that the particular value was an "Output Voltage at Audio Frequency." Codes for the values of voltages, currents, frequencies, powers, resistances etc., are standard abbreviations wherever possible. A substitution of u for the letter  $\mu$ , to indicate "micro", was made for practical key-punch reasons.

As the tabulated sheets were finished, as shown in Figure 11, they were checked and given to key-punch operators. The following IBM equipment was used to assist in the data reduction and in the preparation of the final report: key-punch, verifier, reproducing punch, alphabetic interpreter, alphabetic collator, sorter, and an electric accounting machine (EAM).

The EAM was used extensively to print-out the data. A special wiring panel was made for the data printout. Figure 12 is an example of data printout sheets.

Several types of tabulations were undertaken; the following types were completed: (1) equipment description with emphasis on trouble shooting, alignment, and final test; (2) current types of test equipment, with ranges, (3) vacuum tubes and diodes used in the representative equipment.

Several thousand IBM cards were required to contain the information and many combinations of cards were collated and printed out. Examination of the distributions of frequency, voltage, resistance, power, and current were made. The results of the final data reductions formed part of the basis for specific conclusions.

The 60 items of prime equipment tabulated and key-punched on standard IBM cards and the appropriate technical manuals are listed below. The detailed printout of the data tabulated is to be in the Summary, Appendix A.

| TV-2/U              | Tube Tester        | TM 11-2661              |

The tabulated data for the preceding pieces of equipment selected for study were analyzed, and printed out on summary sheets. These sheets containing the following information were prepared from applicable IBM cards:

- a. Equipment nomenclature and description
- b. Maintenance manual required (TM number)
- c. Frequency range and type of emission or reception
- d. Power requirements
- e. Internal voltage and resistance ranges
- f. Various internal frequencies (intermediate, etc.)
- g. Output power levels
- h. Required test equipment as listed in the technical manuals.

An important part of the tabulation was the listing of the accuracies required in the various readings. From these accuracies, listed in percentages, it is possible to summarize the results, and from this to deduce the required accuracy of a specific measurement module. Following is a summary of accuracy tabulations:

| <u>Type of Measurement</u>    | <u>Accuracy, %</u> |
|-------------------------------|--------------------|
| Voltage                       | 3 to 20            |
| Frequency                     | 0.005 to 1         |
| Resistance                    | 10 to 20           |
| Transmitter output power (RF) | 10 to 20           |
| Receiver output power (AF)    | 5 to 20            |
| Primary power                 | 10                 |

IV Factual Data, A (cont.)

Measurement accuracy of discrete channel frequencies, oscillator frequencies, or intermediate frequencies is high. However, test frequencies specified in determining power output on various bands may be varied 20% without affecting the test. The end use of the test frequency must be determined before the required accuracy can be stipulated. The discussion on frequency groupings (see Paragraph IV,A,5) presents those frequencies which may be combined where required accuracy permits.

As a part of the overall study, vacuum tubes and diodes which are used in the selected pieces of equipment were tabulated along with their use in the equipment. This tabulation was further condensed, and 170 types of vacuum tubes and diodes were summarized. The total usage of each type was also listed. It is noteworthy that eight tube types represent 30% of the total number of tubes used in the equipment studied. A total of 1164 tubes and semiconductor diodes were tabulated. Of this total, 390 were accounted for by the following tube types:

|       |       |

6. Secondary Items in Print-Out

The value of storing the test data on IBM cards is readily apparent when the summary of any one parameter is desired for all the equipment to be tested. In this manner the frequency spectrum of the equipment tabulated, for example, was obtained for study.

The entire frequency spectrum was charted, both from a very general aspect and from the viewpoint of specific pieces of equipment. Figure 6 is a chart of the electromagnetic spectrum covered in the electronic equipment studies, with particular emphasis on discrete test frequencies. Figure 7 shows the spectrum for specific pieces of equipment.

IV Factual Data, A (cont.)

The log scale of Figure 6 covers the frequency spectrum from 10 cps to 10 kmc. An attempt was made, by selective shading, to indicate the frequencies utilized by both frequency-modulated equipment and amplitude-modulated equipment. The audio frequencies associated with these two types are also defined. Intermediate frequencies are separated from radio frequencies. The ranges required of frequency meters and a specific panoramic indicator are shown for comparison.

Figure 7 covers the spectrum from 100 cps to 100 kmc. Representative pieces of tactical electronic equipment, including test equipment, are listed in line with the frequencies covered. The receiver band coverage is indicated by solid lines. The intermediate frequencies are shown except in a few pieces of equipment, with variable IFs (intermediate frequencies). These variable IFs are shown as interrupted lines. Transmitter band coverage is indicated by an interrupted line. In the test equipment section, signal generators are indicated by solid lines and frequency meters are shown as interrupted lines.

One specific use of the data cards was to survey and collate the discrete frequencies in use. A list of frequencies and the number of times used in test procedures was prepared from the card summary. The results of this summary are presented in Figures 13 and 14. These figures illustrate how the collation of the mass of tabulated data was utilized. Appendix B contains the printout of all the data relating to specific frequencies. The collator was set up to remove all cards with the function code of 4 in the second-digit position. Examination of Table 2 reveals that this is the specific code for frequency or phase.

The entire group of cards thus culled were sorted numerically from the lowest frequency to the highest listed frequency, using the low or discrete values. At this time the frequencies were grouped, and from these groupings the bar charts shown in Figures 15 and 16 were generated.

As the study proceeded it became obvious that certain specific frequencies appeared much more often than others, and that certain groups of

IV Factual Data, A (cont.)

frequencies predominated. Many test frequencies were arbitrarily chosen from the various technical manuals. Without affecting the accuracy of the tests, these could be changed from many diverse nearby frequencies to one specific test frequency. This specific test frequency could be a part of a group composing one building block. The practical number of discrete frequencies in one module or block is a design consideration which may be defined as the study continues.

The study of various pieces of test equipment, and the ranges of this equipment, brought out the areas of redundancy. As examples, various multimeters and electronic multimeters all cover approximately the same range and perform approximately the same function. Some, of course, may be used more readily in forward areas since the only power requirements are internal batteries.

In a discussion of signal-generation and signal-measurement equipment, it may be pointed out that the building block concept will permit the interchangeable use of radio-frequency oscillators both as signal generators and as signal-measurement devices by applying the appropriate heterodyning techniques.

The bar graphs of Figures 15, 16, and 17 were prepared in order to show range overlapping in existing test equipment. Non-overlapping areas are also shown in order to present a total comparison of all existing equipment. Clarification should be given to items such as the SG-351/USD-1, the SG-336/U, and the BC-376 signal generators. The SG-351/USD-1 lower-frequency limit is 406 mc, while the upper limit is 420 mc. Clarification of the SG-351/USD-1 was considered necessary because the chart resolution in this frequency range is not adequate to define each megacycle. The SG-336/U is a sweep generator with center frequencies at 30 and 60 mc, and markers at 25, 35, 55, and 65 mc. The BC-376 is a single-frequency generator at 75 mc, and is used for performing certain receiver-antenna tests. The individual equipment range overlapping and the number of bands are not depicted in the graphs. Instead, the upper and lower limits are shown. Since ohmeter ranges are essentially standard (except in specialized equipment), they were not included in the graphs. Output or power

IV Factual Data, A (cont.)

meter ranges in dbm were converted to watts in order to standardize the power meter graph scale.

7. Discussion in Review

The evaluation performed in this first phase of the program has indicated the advisability and the practicality of automatic testing within the framework of a modular, building block system. The examination of 91 items of Signal Corps communication and test equipment provided test data in support of this conclusion.

A decision to automate the maintenance testing is practically inevitable in an era of increasing mobility of ground forces, and increasing numbers of electronic equipment, particularly miniature versions operated by non-technical personnel. Some highly specialized electronic equipment will require more time in order to obtain completely automated testing procedures because of the extremely sophisticated automatic test equipment needed. At present, however, a major portion of even the most complex equipment may be automatically checked. Each item of electronic equipment considered for automatic testing should be evaluated on the following type of basis:

- a. The complexity of the item
- b. The number of these items in the Field Army
- c. The operator skill level required
- d. The need for speed in testing the item
- e. Improvement in supply.

B. SECOND PHASE

The Building Block Study program was logically divided into two parts as a result of the redirection. The second part, or phase, was to be concerned with the compilation of test requirements. The first phase, however, was a comprehensive survey of test requirements plus an analysis of the data and an application exercise. The breadboard, or application exercise, had not been performed at the time of the change in scope, and the analysis of data was curtailed. The preparation of preliminary design parameters, a natural outgrowth of the analysis, was accordingly halted.

---

IV Factual Data, B (cont.)

The second phase then became primarily a review of the Army technical manuals and related documents of prime electronic equipment, preliminary to a summary and an evaluation of the test data obtained. This information will furnish a basis for proceeding with building block system analysis and breadboard application in the future.

Most of the activity in this phase was concerned with securing technical manuals suitable for tabulation and processing. There was a great deal of material reviewed, but a large amount of it was not suitable for tabulation due to its non-technical content.

A shipment of technical manuals for review and tabulation was received early in March 1963 directly from the Commanding Officer, U.S.A. Electronic Research and Development Laboratory, Fort Monmouth, New Jersey. These manuals were ordered by Mr. A. Rosenblum, Chief of the Instrumentation Branch, USAERDL, specifically for use in this program, and are as follows:

- Handbook for Radio Set AN/ARC-51.
- Instruction Book for Radio Set AN/GRC-66 Vol. 2, Part III.
- Instruction Book for Radio Set AN/GRC-66 Vol. 3, Part III.
- Technical Instructions for Radio Set AN/GRC-50.
- ARF Instrumentation and Measurements Techniques Study Report No. 14.
- ARF Instrumentation and Measurements Techniques Study Report No. 15.
- Instruction Book for Radio Set AN/VRC-12.
- Service Test Instruction Manual for Multiplexer Sets AN/TCC-46, -47, Book No. 5.
- Service Test Instruction Manual for Multiplexer Sets AN/TCC-46, -47, Book No. 6.
- Technical Manual for the AN/GRC-106.

These manuals are essentially manufacturers' instruction books, and contain sufficient technical data for review and tabulation. They have been included in the material covered for this report, and their test parameters are listed in the IBM printout sheets (see Appendix C), with the exception of the

IV Factual Data, B (cont.)

two ARF Instrument and Measurements Techniques Manuals (which are not manuals of prime electronic equipment or test equipment). The printout of 18 other pieces of Army prime electronic equipment is also included in the same Appendix as part of the Phase Two tabulation.

1. Nature of the Data Desired

The data tabulation in this, the second phase of the program, has been simplified in line with the redirection of the program. In this version, the tabulations are made only of measurement ranges for prime electronic equipment and specified test equipment to perform the measurements. This means that the four divisions used previously for (1) power requirements, (2) trouble shooting, (3) alignment, and (4) final test are being replaced with the following codes and breakdown:

Code 100-199 Measurement Ranges

The measurement ranges are to be the minimum and maximum for each item measured.

Code 200-299 Test Equipment

All test equipment is that listed in the technical manual as required for maintenance testing of the prime equipment being evaluated.

The measurement ranges are tabulated according to the same code, Table 2, as used before. The ranges listed are the extremes for troubleshooting, testing, and alignment.

The measurement data provides the range information needed for design criteria on the test modules and submodules. By planning the modules to test over the entire range of voltages, for example, with a single module, an economy in the total number of multimeters and electronic multimeters would be effected by substituting the more efficient module in their place. Similarly, the test instrumentation for power measurement (RF, dc or ac), current measurement, frequency measurement (including modulation, FM, AM, sideband, R-F carrier, etc.), resistance-impedance measurement, and any miscellaneous measurement, may be designed from the data tabulated under the measurement ranges.

---

---

IV Factual Data, B (cont.)

The listing of the test instruments required for maintenance of each item of Army electronic prime equipment is an essential part of the data survey. This information is important (1) in establishing the design characteristics of the building-block modules, (2) in furnishing comparative data on the number of pieces, (3) as a base for conventional-system price estimates, and (4) as a record of the testing capability of the conventional testing system. The compilation of this test instrumentation list will preclude any thorough preliminary design preparation for a building-block module testing system, and may be considered a necessary part of the data compilation. Accordingly, the data collection includes the test equipment in a summary beneath the test measurement ranges on the work sheets, and in the same IBM card packet for the particular equipment.

2. Discussion of Test Requirement Compilation

The technical manuals and handbooks have continued to be the test data information source, as they were in the earlier, phase one, part of this program. The securing of manuals covering testing at a fourth- or fifth-echelon level has become increasingly difficult, however, as mentioned in the monthly progress reports. The manuals written for lower level testing do not have the measurement range data needed for this study. They are set up to be "check procedures" on a "go no-go" basis instead. Many are for use with large built-in "test consoles." The supply of manuals of proper technical depth is good for electronic equipment maintenance as set up by the U.S. Army Signal Corps (now the USAELDR). These handbooks have been used successfully.

A large number of technical bulletins and manuals have been reviewed in the effort to present a complete tabulation of test requirements for Army prime electronic equipment. Most of the manuals reviewed in this latter part of the program proved to be inadequate. The Department of the Army Pamphlet DA No. 310-4 Index of Technical Manuals, Technical Bulletins, etc. was used to obtain the TM, TB, or TO numbers. These numbers were then used in ordering the documents. Many were ordered through the Aerojet-General Corporate Engineering

IV Factual Data, B (cont.)

Documentation Office, and others were borrowed from the Western Regional Office of the U.S. Army Signal Supply Agency in Pasadena, California, or reviewed directly in their library.

A great many of the Army Ordnance technical manuals were found to be classified Confidential and some Secret, especially those pertaining to radar equipment. As classified material lies outside the scope of this program, these manuals could not be used for test requirement review and tabulation. The newer equipment is in general more subject to security classification.

The USD-2 Surveillance System Airborne Drone program was reviewed at the Aerojet-General plant in Downey, California for possible use in this Building Block Study. The following unclassified service test manuals were obtained from the Publications Department of the Downey Plant:

STM-10-Operator and Organizational Maintenance Manual  
STM-12-Operator's Manual  
STM-13-Organizational Maintenance Manual.

These manuals contain basic information on the operation of the drone system, but the test data parameters are not sufficiently well defined for tabulation and transfer to the IBM cards. There is a good potential in the drone operation for testing with an integrated building-block module system. Later manuals should be adequate in the presentation test data requirement information. A large portion of the drone functions are classified, however, such as the radar equipment, the infrared instrumentation, and the integrated guidance and control equipment. If the test data for these equipments would be downgraded to Unclassified, the possibilities for a building block test system application would be very good.

The difficulty of securing the type of Army manuals needed led to the consideration of using Air Force technical manuals. Accordingly, at the suggestion of the USAELRDL office, Air Force documents equivalent to the Electronics Command Technical Manuals were ordered for study. About 100 manuals

IV Factual Data, B (cont.)

were requested from the U.S. Air Force at Rome, N.Y. and Dayton, Ohio, and subsequently received 30 to 60 days later. Some of them were reviewed and tabulated. However, under later instruction from Mr. A. Rosenblum, on his visit to Aerojet in February, work on the Air Force manuals was suspended in order that the limited time remaining could be devoted to the Army material, and the Air Force tabulations were omitted from this report.

There were 24 items of prime Army electronic equipment tabulated and recorded on IBM cards in this second phase (Phase B) of the program. The six items of equipment reviewed in manuals received from USAELRDL are included in this group. The 24 items are listed in order below:

| Nomenclature    | Description               | Technical Manual                             |
|-----------------|---------------------------|--|
| AM/1805/FRC-55B | R-F Amplifier             | TO31R2-2FRC-412                              |
| AN/AMQ-7        | Humidity-Temperature Set  | TO12M3-2AMQ7-2                               |
| AN/AMR-1A       | Radiosonde Receptor       | TO12M1-2AMR1-2                               |
| AN/AMT-6D       | Radiosonde                | TO12M4-2AMT6-11                              |
| AN/ARC-51       | Radio Set                 | Naval Weapons Bureau                         |
| AN/FPN-33       | Radar Set                 | TM 11-1538                                   |
| AN/FRR40 and 41 | Radio Receiving Set       | TO31R2-2FRR40-6                              |
| AN/GPA-23       | Radar, Computer-Tracking  | TO31P1-2GPA23-2                              |
| AN/GRA-30       | Transmitter Control Group | TO31R2-2GRA30-2                              |
| AN/GRC-50       | Radio Set                 | Technical Instructions<br>(USAELRDL)         |
| AN/GRC-66       | Radio Set                 | Instruction Book, Vol. II,<br>III (USAELRDL) |
| AN/GRC-106      | Radio Set                 | Technical Manual (General<br>Dynamics Corp.) |
| AN/MRR-6        | Receiving Set, Radio      | TO31R2-2MRR6-2                               |
| AN/MRT-7        | Transmitting Set, Radio   | TO31R2-2MRT7-2                               |
| AN/PRS-4        | Detecting Set, Mine       | TM-9541                                      |
| AN/TCC-46, -47  | Multiplexer Sets          | Raytheon Service Test<br>Instruction Manual  |

## IV Factual Data, B (cont.)

| Nomenclature      | Description       | Technical Manual                      |
|-------------------|-------------------|---------------------------------------|
| AN/TRC-66         | Radio Set         | TO31R5-2TR66-2                        |
| AN/TRC-68(VRC-64) | Radio Set         | TM11-5820-222-35                      |
| AN/ULT-T2         | Trainer, Radar    | TM11-6940-205-15                      |
| AN/VRC-12         | Radio Set         | Instruction Book<br>(Avco Mfg. Corp.) |
| CU/547/GR         | Antenna Coupler   | TO31R1-2GR-142                        |
| IM-108/PD         | Radiacrometer     | TM11-6665-200-35                      |
| KWT-6             | Transceiver       | TO31R2-4-127-9                        |
| T-265/FRC-10      | Radio Transmitter | TO31R2-2FRC10-26                      |

3. Review of Major Items in Printout

The test parameters and the test instruments for the 24 items tabulated in this phase of the program are shown in Appendix C. The measurement ranges, coded according to the Key in Table 2 and the units in Table 1, are listed under each item of equipment, and are followed in each case, as before, by the list of test equipment prescribed in the manuals.

a. A survey of the voltage ranges and the frequency ranges to be found in these pieces of equipment was made and graphs drawn. Figure 18 illustrates in bar graph form the radio frequency ranges in each case. The audio frequency ranges, representative of a smaller portion of equipment, are drawn in the bar graph of Figure 19. The D-C voltage ranges are featured in Figure 20, and the A-C voltage ranges in Figure 21. The equipment number is marked on each measurement range. The range data from the graphs has been consolidated for convenience into the following summary of total range spread and discrete voltages and frequencies most commonly used.

|  |                 |
|--|-----------------|
| Audio frequency, over-all range            | 50 cps - 100 kc |
| Discrete audio frequency most used         | 1000 cps        |
| Widest audio range of any single equipment | 50 cps - 100 kc |

## IV Factual Data, B (cont.)

|   |                           |
|---|---------------------------|
| Radio frequency, overall range                | 100 kc - 13.5 gc          |
| Discrete radio frequency most used            | 400 mc                    |
| Widest r-f range of any single equipment      | 10 mc - 13.5 gc           |
| Percent of total equipment in microwave range | 25%                       |
| D-C voltage, over-all range                   | 0.01 v, dc - 12 kv, dc    |
| D-C voltage, range most used                  | 2 v, dc - 125 v, dc       |
| Widest d-c range of any single equipment      | 0.02 v, dc - 12 v, dc     |
| A-C voltage, overall range                    | 0.02 v, rms - 6.5 kv, rms |
| A-C voltage range most used                   | 6.3 v, rms - 115 v, rms   |
| Widest d-c range of any single equipment      | 1.4 v, rms - 6.5 kv, rms  |

The information on a-c or d-c current, d-c ohms, impedance, power, pulse, etc. has been consolidated into the following ranges. The population factor of usage for these measurements is low, and for this reason they have not been converted into graph form.

|                       |  |
|-----------------------|--|
| D-C resistance range  | 0.06 ohms - 150 megohms                      |
| D-C current range     | 10 $\mu$ a - 400 ma                          |
| A-C current range     | 0.5 - 6.0 amp                                |
| R-F power range       | 1.0 mw - 30 kw peak envelope<br>1 kw average |
| A-C power range       | 50 mw - 7.715 kw                             |
| Pulse width           | 1 $\mu$ s - 1.5 millisec                     |
| Pulse frequency       | 20 cps - 550 cps                             |
| Pulse power           | 140 watt (min. peak power)                   |
| Pulse amplitude range | 1.3 v - 130 v P-P                            |
| Pulsating d-c range   | 16 - 60 v                                    |
| Pulse voltage         | 1.4 kv discrete                              |
| Audio voltage         | 1 mv, rms - 2.5 v, rms<br>1.5 v - 42 v P-P   |
| I-F frequency         | 297 kc - 457 kc                              |

IV Factual Data, B (cont.)

A comparison between the equipment surveyed in this phase and that in phase one shows little change in the overall measurement ranges. There is, however, a modest shift upward in frequency. The newer equipment reflects use of higher frequencies with the 400-mc area predominant. Test equipment and test methods have been changing to meet higher-frequency requirements, especially for single-sideband-suppressed carrier equipment which has been coming into use recently. Communications microwave equipment, such as the AN/TRC-66 Radio Set, requires a substantial amount of microwave test equipment, as shown in the test equipment listed under the AN/TRC-66 printout in Appendix C.

The AN/TCC-46 and -47 tabulation is the first multiplexer system reviewed in this program. Its testing requirements are different because of the time division multiplex-pulse code modulation (TDM-PCM) pulse train operation.

Newer types of test equipment are more noticeable in the list of test instruments called out in Appendix C for the phase two prime equipment. Many items apparently had not been assigned AN numbers at the time the manuals were written, and are listed by the manufacturer's name and number.

A testing system requires flexibility to avoid an early obsolescence from the continuing changes in equipment. With the building block module system, the provision for modernizing of a specific module will be relatively simple, by substituting the redesigned sub-module or module replacement.

4. Test Data Extraction from the EAM Cards

The usefulness of the test data storage on the EAM cards is illustrated by the voltage measurement ranges listed in Appendix D. These voltages were rapidly sorted from the punch cards summarized in Appendix C. Any desired parameter may be sorted in a similar manner, and the information then printed out automatically from the sorted cards.

IV Actual Data, B (cont.)

The voltage listing of Appendix C was sorted by use of the function code explanation, Table 2, and the sample test requirements data work sheet, Figure 18. The selection of a "blank" for column eight of the Figure 18 data work sheet sorts out the equipment nomenclature. Then by selection of 1 and 2 (from Table 2) in column 24 draws the input and output entries. Next the selection of 1 for column 25 limits the sorting to voltages, and then the selection of 1 and 2 for column 26 draws out both the D-C and the A-C. Thus the input and the output voltage cards, for both A-C and D-C, are sorted out. For clarity the sorting may be shown in table form as follows:

|                            | Column No.          |
|----------------------------|---------------------|
|                            | 8    24    25    26 |
| Title Page Selection       | "blank"             |
| Input and Output Selection | 1,2                 |
| Voltage Selection          | 1                   |
| D-C and A-C Selection      | 1,2                 |

By restricting the column 24 sorting to number one (1), and column 25 and 26 left as above, the cards would be sorted only for Input Voltages (both A-C and D-C). In the same fashion, any type of data on the cards may be sorted quickly and then printed out automatically on the EAM machine. The versatility of the EAM card system thus becomes readily apparent.

V. OVERALL CONCLUSIONS

The review of the technical manuals and the evaluation of the test requirements illustrates the existing potential for automated building-block module test systems in the field. There are many advantages to be gained in adopting this type of test instrumentation, from the standpoint of operational, technical, and financial factors, as outlined below.

A. OPERATIONAL ADVANTAGES

1. Greater portability and handling ease
2. Reduced "set-up" and "take-down" time

V Overall Conclusions, A (cont.)

3. Improved ruggedness (due to solid-state circuitry)
4. Reduced operator training time
5. Lessened operator skill requirements
6. Reduction of total testing time
7. Permanent record of test measurements
8. Uniform programmed test procedures.

B. TECHNICAL ADVANTAGES

1. Greater test repeatability (due to uniform test set-ups and solid state circuitry).
2. Improved reliability
3. Reduced and simplified maintenance.

C. FINANCIAL ADVANTAGES

1. Lower overall cost (due to elimination of redundant test instruments).
2. Greater system efficiency, based on operational and technical advantages in A and B, above.
3. Simplicity of modernization by sub-module substitution.

A practical approach to designing an automatic, integrated building block system investigated as a sample case was the final test procedure for the AN/PRC-6. An automated test procedure for the building-block method, drawn up and compared to the conventional procedure, paragraph IV,A,4,b of this report, shows the possible reduction and simplification of steps the building-block system offers. This application exercise was not carried to the breadboard design and fabrication, but was advanced almost to this point before the program was redirected.

The data collected through the two phases of the program represents a tabulation of technical manuals covering 85 pieces of prime Army electronic equipment. The test measurement ranges and the list of applicable test instruments in each case are key-punched on EAM cards, available for convenient recall on the sorting machine and printer. Also the information is printed out in the summaries in Appendixes A, B, C, and D for review.

VI. RECOMMENDATIONS

First, obtain the Test Requirements Data for all the pertinent Army prime electronic equipments used in the field, which have not already been tabulated on this program. This would probably have to be done by the Army, working internally through the Commands, extending the search for technical manuals or service handbooks into the laboratories and to the equipment manufacturer, if necessary.

Secondly, use the additional manuals and handbooks to complete the test requirements tabulation. With this data, an evaluation of the total testing need, the total test instrumentation scope, and the technical problems involved could be made, using the EAM cards for detailed data extraction.

Thirdly, undertake an advanced study and application exercise, establishing the combination of test instrumentation desired in a given building block module system and the design characteristics which must be met, thus completing the design criteria.

VII. IDENTIFICATION OF KEY TECHNICAL PERSONNEL

The following key technical personnel were employed on this project. The assignments and percentages of time are as indicated:

| <u>Name and Title</u>                  | <u>Responsibility or Work Assignment</u> | <u>Time Allocated to Project</u> |
|--|--|----------------------------------|
| R. S. Megerle, Manager Support Systems | Task Manager                             | 5%                               |
| R. A. Orr<br>Principal Engineer        | Project Manager                          | 5%                               |
| B. W. Vinton<br>Asst. Senior Engineer  | Project Engineer                         | 50%                              |
| N. A. Simpson<br>Test Engineer (A)     | Asst. Project Engineer                   | 75%                              |

TABLE 2  
FUNCTION CODE EXPLANATION

| COL.  | 24  | 25  | 26  | 27  |
|-------|-----|-----|-----|-----|
| DIGIT | 0   | 0   | 0   | 0   |
|       | 1st | 2nd | 3rd | 4th |

1st Digit:      1 = Input (from a stimulus generator)  
                  2 = Output (to a measuring instrument)

2nd Digit:      1 = Voltage  
                  2 = Current  
                  3 = Power  
                  4 = Freq. and phase  
                  5 = Modulation and intelligence  
                  6 = Time  
                  7 = Impedance  
                  8 = (Open)  
                  9 = Miscellaneous accessories

3rd Digit:      1 = DC  
                  2 = AC  
                  3 = Audio  
                  4 = IF  
                  5 = RF  
                  6 = Microwave  
                  7 = Pulse

4th Digit:      1 = AM  
                  2 = FM  
                  3 = Pulse  
                  4 = Complex wave
